Technical Committee

CMIP Specification
for the
M4 Interface

af-nm-0027.000

September, 1995

Contents

1. Introduction

This document specifies an ATM information model that provides a formal representation of the information exchanged between a managed system (e.g., an ATM NE) and a managing system using Guidelines for the Definition of Managed Objects (GDMO) templates, Abstract Syntax Notation One (ASN.1) syntax, and the Common Management Information Service Element (CMISE) services and protocol. This information model was specifically designed to meet the criteria defined in the ATM Forum's M4 Interface Specification[1].

The model presented in this document reuses existing ITU-T Recommendations and other standards on information modeling where applicable. The ITU-T Recommendations referenced in this model are as follows:

- ITU-T Recommendation G.774 and G.774-01[2]
- ITU-T Recommendation M.3100[3]
- ITU-T Recommendation Q.822[4]
- ITU-T Recommendation X.721[5]
- ITU-T Recommendation X.739[6]

Other information modeling documents such as Bellcore's GR-836-IMD[7] and ANSI's T1.247[8] have been applied here for specific objects that have not yet been addressed in ITU-T.

The information model presented in this document was defined specifically to meet the functional requirements of the M4 Interface as set forth by the ATM Forum in 94-388R4[1]. When possible, the ATM Forum drew upon existing ATM CMIP modeling work in this area. Two models in particular that served as significant sources of input in the creation of this Information Model were ETSI's NA5-2210[9], "B-ISDN Management Architecture and Management Information Model for the ATM cross-connect", and Bellcore's TA-NWT-001114 Issue 2[10], "Generic Requirements for Operations Interfaces Using OSI Tools: ATM/Broadband Network Management".

The focus of this specification is on the definition of a Management Information Base (MIB) for CMIP implementations of the M4 Interface. See Annex A for recommended communication stacks to support the CMIP-based M4 Interface.

2.   ATM NE Management Information Model

This document defines an information model that provides a formal representation of the information exchanged across the CMIP-based interface used to manage ATM Network Elements (NEs).

Note that the terminology used in the information modeling community to describe ATM/SDH based networks is not always the same as the terminology used by the broader range of ATM/SDH subject matter experts. Table 2-1 has been provided to assist the reader in understanding the mapping between these terms.

Table 2-1: Mapping of Equivalent Terms

Information Modeling Term	Commonly Used Equivalent
ATM Virtual Channel (VC) Connection	ATM Virtual Channel Link (VCL)
ATM Virtual Channel (VC) Trail	ATM Virtual Channel Connection (VCC)
ATM Virtual Path (VP) Connection	ATM Virtual Path Link (VPL)
ATM Virtual Path (VP) Trail	ATM Virtual Path Connection (VPC)
Inter-NNI	Broadband Inter Carrier Interface (BICI)
Intra-NNI	Broadband Inter Switching System Interface (BISSI)
SDH Administrative Unit Group (aug)	SONET STS-3 Group
SDH Administrative Unit 4 (au4) Connection	SONET STS-3c Channel
SDH Regenerator Section (rs) Connection	SONET Section
SDH Multiplex Section (ms) Connection	SONET Line
SDH Virtual Container 4 (vc4) Trail	SONET STS-3c Path

The similarity in the two sets of terminology can be a source of confusion for the first time reader, especially the terminology used to describe ATM VPs and VCs. The reader is urged to become familiar with the above mapping before delving into the details of the information model presented here.

Figures 2-1a, b, c and d illustrate the containment relationships between the managed object classes identified here for support of ATM NE management. Note that an arrow pointing from one object class to another object class represents the subordinate/superior relationship used as the basis for naming managed object classes.

Figures 2-2a, b, c, d, e, and f illustrate the inheritance relationships between these managed object classes.

REGISTERED AS {atmfM4ObjectClass 2};

atmCrossConnectionBeh BEHAVIOUR
    DEFINED AS
        "For point-to-point ATM VP and VC cross-connections, this managed object identifies the cross-connection
        relationship between two instances of the vpCTPBidirectional object class or vcCTPBidirectional object
        class, respectively. The vpCTPBidirectional or vcCTPBidirectional object instances being cross-connected

are identified by the fromTermination and toTermination attributes inherited from the crossConnection object class defined in ITU-T Recommendation M.3100.

For multipoint ATM VP and VC cross-connections, this managed object identifies the cross-connect relationship between an instance of the vpCTPBidirectional object class or vcCTPBidirectional object class and an instance of the multipointBridge object class. For multipoint ATM VP and VC cross-connections, each vpCTPBidirectional or vcCTPBidirectional object instance connected to the multipointBridge object is identified by the fromTermination attribute of the atmCrossConnection object, while the instance of the multipointBridge object class is identified by the toTermination attribute. Note that multipoint ATM cross-connections are established by cross-connecting multiple instances of the vpCTPBidirectional or vcCTPBidirectional object class (each with its own atmCrossConnection object) to a single instance of the multipointBridge object class.

The administrativeState attribute inherited by this managed object may be used by the managing system to inhibit (lock) and allow (unlock) ATM cell flow through the ATM cross-connection being represented.

The recoveryType attribute identifies whether the ATM cross-connection is recoverable (default) or non-recoverable. Recoverable cross-connections remain intact regardless of the operational state of the cross-connection. Non-recoverable ATM cross-connections are cross-connections that are automatically released by the managed system upon detection of a service affecting failure.

Instances of this object class are automatically created and deleted by the managed system based on operations performed on the containing atmFabric or atmMpFabric object.

All ATM VP/VC cross-connections are, by definition, bi-directional; therefore, the directionality attribute, inherited from the crossConnection object class, shall be set to the fixed value of bidirectional.

The value of the signalType attribute is for further study. ";

atmFabricBeh BEHAVIOUR
     DEFINED AS

"This object class represents the function of managing the establishment and release of ATM cross-connections.

Administrative State:

-   Unlocked: The atmFabric is allowed to perform its normal functions. ACTIONS will be accepted to setup or remove cross-connections.

-   Locked: The atmFabric is not allowed to perform its normal functions. No ACTIONS will be accepted. No new cross-connection can be setup or removed.

Operational State:

-   Enabled: When the atmFabric is in the enabled operational state, it may be fully operational or partially operational (partially operational is indicated by the availability status attribute).

-   Disabled: The atmFabric is incapable of performing its normal function. For instance, the managing system will not be able to setup or remove any cross-connection.

Availability Status, the supported values are:

-   Degraded: The atmFabric is degraded in some respect. For instance, the atmFabric cannot perform the function of establishing new cross-connections while it can still accept ACTIONs to tear down existing connections. The atmFabric remains available for service (i.e. its operational state is enabled) while it is degraded.

-   Empty SET (none of the availableStatus conditions exist).

One instance of the atmFabric object class shall be automatically created by the managed system upon completion of system initialization. Further creation and deletion of such objects is not supported.";

```

" The multipointBridge object class is a class of managed objects that represent the multipoint bridging function used to support multipoint VP/VC cross-connections. An instance of this object class shall exist for each multipoint VP/VC cross-connection supported by the managed system.

Instances of this object class shall be explicitly created and deleted by the managing system using the CMIS M-CREATE and M-DELETE services, respectively. Instances of this object class shall not be deleted until all associated instances of the atmCrossConnection object class are also deleted. When explicitly created by a managing system, the primaryCTP and multipointConnectionType attributes shall be set to NULL and the commonCTPs attribute shall be set to the EMPTY SET.

This object class is used to support four types of multipoint VP/VC connections. They are as follows:

- broadcast
- merge
- composite
- full multipoint

The primaryCTP attribute identifies the vpCTPBidirectional or vcCTPBidirectional object that generates traffic to broadcast and/or receives merged traffic for broadcast, merge, or composite multipoint cross-connection types. For full multipoint connections (i.e., all legs communicate with all other legs),

the value of this attribute shall be set to NULL. The primaryCTP attribute value shall remain fixed during the life of the multipoint cross-connection.

The commonCTPs attribute identifies all legs of the multipoint connection except the leg identified via the primaryCTP attribute. This attribute provides a pointer to one or more instances of the vpCTPBidirectional object class or vcCTPBidirectional object class. For full multipoint cross-connections, all the legs of the multipoint cross-connection shall be identfied by this attribute. The legs represented by the commonCTPs attribute may be added or removed from an existing multipoint connection by performing the addTpsToMultipointBridge and removeTpsFromMultipointBridge operations, respectively, on the appropriate instance of the atmMpFabric object class.

The administrativeState attribute may be used by the management system to inhibit (lock) and allow (unlock) ATM cell flow through all multipoint cross-connections supported by the multipointBridge.";

2.5. Actions

2.5.1. addTpsToMultipointBridge

```
addTpsToMultipointBridge ACTION
    BEHAVIOUR addTpsToMultipointBridgeBeh;
    MODE CONFIRMED;
    WITH INFORMATION SYNTAX AtmMIBMod.AddTpsToMultipointBridgeInfo;
    WITH REPLY SYNTAX AtmMIBMod.AddTpsToMultipointBridgeReply;
REGISTERED AS {atmfM4Action 1};
```

```
addTpsToMultipointBridgeBeh BEHAVIOUR
    DEFINED AS
```
"This action is used to add one or more vpCTPBidirectional objects or vcCTPBidirectional objects to the identified multipoint connection.

Supplied with this action is the following information:

New CTPs - This parameter identifies the additional CTPs (i.e., the vpCTPBidirectional or vcCTPBidirectional object instances) to add to the existing multipoint connection.

MultipointBridge - This parameter identifies the instance of the multipointBridge object class to which the additional legs need to be connected.

If the request is granted, the commonCTPs attribute, in the multipointBridge object, shall be reset to reflect the new legs added to the multipoint connection. ";

2.5.2. connect

connect ACTION
    BEHAVIOUR connectBeh;
    MODE   CONFIRMED;
    WITH INFORMATION SYNTAX AtmMIBMod.ConnectInformation;
    WITH REPLY SYNTAX AtmMIBMod.ConnectReply;
REGISTERED AS {atmfM4Action 2};

connectBeh BEHAVIOUR
    DEFINED AS
"This action is used to establish a point-to-point ATM connection two between termination points. The termination points to be connected can be identified explicitly by specifying the associated vcCTPBidirectional object or vpCTPBidirectional object, or by specifying the charcteristics of each termination point. Multiple point-to-point connections may be requested with a single connect ACTION.

If a valid end point descriptor is provided and the connect request can be successfully carried out, the NE would reserve the necessary resources such as the VPI and/or VCI value, and automatically create the necessary VP/VC termination points (e.g., the VP CTPs, VP TTPs, and VC CTPs) for the cross-connection.

The result, if successful, always returns an explicit list of termination points.

Successful execution of this action would result in the creation of an instance of the atmCrossConnection object. This cross-connection object has the fromTermination and toTermination attributes pointing to the two termination points. The administrativeState and recoveryType attributes in the cross-connection object are initialized according to the values provided in the action request information. If the administrativeState parameter is omitted, the administrative state will be set to 'unlocked'. If the recoveryType parameter is omitted, the recovery type will be set to recoverable.

If the administrativeState in the atmCrossConnection object is unlocked, the upstreamConnectivityPointer and downstreamConnectivityPointer in the two termination points are set to the local distinguished name of the (peer) termination point to which it is connected. Also, the crossConnectionObjectPointer in the termination points shall point to the atmCrossConnection object.

This action will fail if any of the termination points specified are already involved in a cross-connection, any of the termination point descriptors specified cannot be satisfied, or the two termination points do not have compatible termination point descriptors.";

2.5.3. connectMultipointBridge

connectMultipointBridge ACTION
    BEHAVIOUR connectMultipointBridgeBeh;
    MODE CONFIRMED;
    WITH INFORMATION SYNTAX AtmMIBMod.ConnectMultipointBridgeInfo;
    WITH REPLY SYNTAX AtmMIBMod.ConnectMultipointBridgeReply;
REGISTERED AS {atmfM4Action 3};

connectMultipointBridgeBeh BEHAVIOUR

DEFINED AS

"This action is used to establish a multipoint connection between vpCTPBidirectional or vcCTPBidirectional objects. Four types of multipoint connections can be established using this action: broadcast, merge, broadcast/merge (composite), and full multipoint. The multipointConnectionType attribute of this action is used to identify the desired connection type. Note that this action will result in the cross-connection of CTP objects to an instance of the multipointBridge object.

Also supplied with this action is the following information:

Primary CTP - This parameter identifies a termination point (vpCTPBidirectional or vcCTPBidirectional object) or termination point descriptor for the termination point that generates traffic to broadcast and/or receives merged traffic for broadcast, merge, or composite multipoint connection types. For full multipoint connections (i.e., all legs communicate with all other legs), the value of this attribute shall be set to NULL. The termination point identified by this parameter shall serve as the basis for the primaryCTP attribute of the multipointBridge object.

Common CTPs - This identifies termination point descriptor or CTP object instances (vpCTPBidirectional object class or vcCTPBidirectional object class) of all legs of the multipoint connection except the leg identified via the primaryCTP attribute. For full multipoint cross-connections, all the legs of the multipoint cross-connection shall be identfied by this attribute. The termination points derived from this parameter shall serve as the basis for the commonCTPs attribute of the multipointBridge.

Recovery Type - This parameter indicates if the multipoint session should be recovered in case of service interruption. This parameter serves as the initial values for the recoveryType attribute in all the associated cross-connection objects.

Administrative State - This parameter will be used as the initial value for the administrativeState attribute in multipointBridge and its associated cross-connection objects.

The action will fail if the primaryCTP is specified but cannot be connected or none of the commonCTPs can be connected. If the action is accepted, the result would return the primaryCTP termination point, the connected common CTPs, and a problem cause for each of the non-connected common CTPs.";

2.5.4. disconnect

```
disconnect ACTION
    BEHAVIOUR disconnectBeh;
    MODE   CONFIRMED;
    WITH INFORMATION SYNTAX      ASN1DefinedTypesModule.DisconnectInformation;
    WITH REPLY SYNTAX ASN1DefinedTypesModule.DisconnectResult;
REGISTERED AS {atmfM4Action 4};
```

disconnectBeh BEHAVIOUR
DEFINED AS
"This action is used to take down a point-to-point cross-connection. The connection to be taken down is specified by identifying a termination point of the connection. The other termination point of the point-to-point connection is implicitly disconnected as well and the cross-connection object is deleted. The connectivity pointers in the disconnected termination points will be set to NULL as a result of this action. Disconnection of multiple point-to-point connections can be requested by providing multiple CTP

object instances in the DisconnectInformation. Each component in the DisconnectResult sequence provides the disconnection result for the corresponding components of the DisconnectInformation sequence.

This action shall not result in the deletion any of the termination point objects to disconnect.";

2.5.5. disconnectMultipointBridge

disconnectMultipointBridge ACTION
    BEHAVIOUR disconnectMultipointBridgeBeh;
    MODE CONFIRMED;
    WITH INFORMATION SYNTAX AtmMIBMod.DisconnectMultipointBridgeInfo;
    WITH REPLY SYNTAX AtmMIBMod.DisconnectMultipointBridgeReply;
REGISTERED AS {atmfM4Action 5};

disconnectMultipointBridgeBeh BEHAVIOUR
    DEFINED AS
"This action is used to release a multipoint cross-connection. Supplied with this action is the instance of the multipointBridge object supporting the multipoint cross-connection.

If any of the commonCTPs cannot be disconnected, the primaryCTP, if any, should not be disconnected. If the multipointBridge is not completely disconnected, the action result would indicate which commonCTPs have been disconnected and which commonCTPs are not disconnected and why.";

2.5.6. loopbackOAMCell

loopbackOAMCell ACTION
  BEHAVIOUR loopbackOAMCellBeh;
  MODE CONFIRMED;
  WITH INFORMATION SYNTAX AtmMIBMod.LoopbackOAMCellInfo;
  WITH REPLY SYNTAX AtmMIBMod.LoopbackOAMCellReply;
REGISTERED AS {atmfM4Action 6};

loopbackOAMCellBeh BEHAVIOUR
  DEFINED AS
" This action is used to request a vpCTPBidirectional, vcCTPBidirectional, vpTTPBidirectional, or vcTTPBidirectional object to insert (in the outgoing direction) a loopback OAM cell into the ATM cell stream and verify its return.

Supplied along with this action is the loopbackLocation parameter. This parameter identifies the downstream vpCTPBidirectional, vcCTPBidirectional, vpTTPBidirectional, or vcTTPBidirectional object instance responsible for looping back the OAM cell. The value of TRUE-NULL (default) can be used to request the end-point of the ATM connection or connection segment to loopback the OAM cell. Also supplied with this parameter is an indication as to whether or not the OAM Loopback Cell to be inserted shall be of the segment type or end-to-end type.";

2.5.7. removeTpsFromMultipointBridge

removeTpsFromMultipointBridge ACTION
    BEHAVIOUR removeTpsFromMultipointBridgeBeh ;
    MODE CONFIRMED;
    WITH INFORMATION SYNTAX   AtmMIBMod.RemoveTpsFromMultipointBridgeInfo;
    WITH REPLY SYNTAX AtmMIBMod.RemoveTpsFromMultipointBridgeReply;
REGISTERED AS {atmfM4Action 7};

removeTpsFromMultipointBridgeBeh BEHAVIOUR
    DEFINED AS
"This action is used to remove one or more legs (leaf CTPs) from the identified multipoint connection.

Supplied with this action is the following information:

Existing CTPs - This parameter identifies the existing CTPs to remove from the multipoint connection.

MultipointBridge - This parameter identifies the instance of the multipointBridge object class from which the identified legs should be removed (disconnected).

If the request is granted, the commonCTPs attribute, in the multipointBridge object, shall be reset to reflect the remaining legs of the multipoint connection. ";

Annex A : Communications Support for the CMIP M4 Interface

In order to promote interoperability, this Annex describes recommended communications stacks to support the CMIP M4 Interface. These recommendations are depicted in Figure A-1 below.

A.1. Protocol Profiles for OSI Stacks

ITU-T Recommendations Q.812 and Q.811 define the protocol profiles for the Q3 interface as defined in Recommendation M.3010.

Implementations of the CMIP M4 Interface that use OSI protocol stacks, should implement the Q3 interface as defined in Recommendation Q.812 for transaction type services (CMISE), and implement supporting lower layer services as defined in Recommendation Q.811.

Note that Recommendations Q.811 and Q.812 are currently being revised with the intention to base the next editions on International Standard Profiles (ISPs) including those of the AOM1x series.

A.2. Protocol Profiles for TCP/IP Stacks

A.2.1. Upper Layer Profiles for TCP/IP Stacks, Layers 5-7

Implementations of the CMIP M4 Interface that use TCP/IP protocol stacks, should implement the OSI upper layers (5-7) as defined in Recommendation Q.812 for transaction type services (CMISE).

A.2.2. Lower Layer Profiles for TCP/IP Stacks, Layers 3-4

Implementations of the CMIP M4 Interface that use the TCP/IP protocol stack, should implement the ISO TP0 protocol on top of TCP/IP as defined in RFC1006.

A.2.3. Lower Layer Profiles for TCP/IP Stacks, ATM Layer

Implementations of the CMIP M4 Interface that use the TCP/IP protocol stack over ATM, should implement IP over AAL5/ATM as defined in RFC1577 using the LLC/SNAP Encapsulation method defined in RFC1483.

A.3. Interim Protocol Profile using CMOT

In order to support early deployment of the CMIP M4 Interface, some implementations may temporarily use the CMOT protocol stack. Implementations of the CMIP M4 Interface that use the TCP/IP protocol stack, may optionally implement the CMOT profile defined in RFC1095[1].

---

[1] Note: RFC1095 has been declared obsolete by the IETF having been replaced by RFC1189, which itself has been classified as a "Historic" RFC with "Not Recommended" status. The option to use a CMOT profile will be removed in the next edition of this specification.
